Ultrasound systems are especially useful in estimating blood velocities in the human body because they are non-invasive and can display an estimate in real time. This book offers a comprehensive treatment of this relatively new, important technology. The book begins with an introduction to ultrasound, flow physics, and the circulatory system.

Determination of blood velocities for color flow mapping systems involves both stationary echo canceling and velocity estimation. Often the stationary echo canceling filter is the limiting factor in color flow mapping and the optimization and further development of this filter is crucial to the improvement of color flow imaging.

Estimation of Blood Velocities Using Ultrasound: A Signal ...

In medical ultrasound systems, spectral Doppler is a powerful tool for non-invasive estimation of velocities in blood vessels (see, e.g., and the references therein). The data for the estimation is created by focusing the ultrasound transducer array along a single direction and sampling data at the depth of interest.

In this work, we have opted to use a solid phantom to test our methods over a large range of velocities to avoid problems of Brownian motion and pulsating flow associated with the flow phantoms. The M-mode signal was collected using instrumentation discussed in . The performance of the PCA-based velocity estimation method was tested using 32-point signals with both the uniform and nonuniform sampling patterns described previously.
